

## Project 06

1. Tell what machine you ran this on.

```
rabbit ~ 1001$ lscpu
Architecture:          x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:            Little Endian
CPU(s):                32
On-line CPU(s) list:   0-31
Thread(s) per core:    2
Core(s) per socket:    8
Socket(s):             2
NUMA node(s):          2
Vendor ID:             GenuineIntel
CPU family:            6
Model:                63
Model name:            Intel(R) Xeon(R) CPU E5-2630 v3 @ 2.40GHz
Stepping:              2
CPU MHz:               1282.177
CPU max MHz:           3200.0000
CPU min MHz:           1200.0000
BogoMIPS:              4800.04
Virtualization:        VT-x
L1d cache:             32K
L1i cache:             32K
L2 cache:              256K
L3 cache:              20480K
NUMA node0 CPU(s):     0,2,4,6,8,10,12,14,16,18,20,22,24,26,28,30
NUMA node1 CPU(s):     1,3,5,7,9,11,13,15,17,19,21,23,25,27,29,31

2. Show the table and graphs

DATASIZE	LOCALSIZE 8	LOCALSIZE 32	LOCALSIZE 64	LOCALSIZE 128	LOCALSIZE 256
4096	49.47	45.99	57.72	57.3	38.07
16384	163.45	188.83	211.56	235.07	154.07
65536	168.76	260.01	292.57	208.71	236.57
262144	323.11	460.96	330.17	423.2	442.54
1048576	702.51	1678.93	1495.79	1426.48	1466.26
4194304	1075.7	2664.01	3025.45	3471.15	3648.05

Performance vs. DATASIZE with colored lines of LOCALSIZE

Performance vs. LOCALSIZE with colored lines of DATASIZE

3. What patterns are you seeing in the performance curves?

The first graph shows the relationship between performance and the size of the data. We can tell that larger DATASIZE contributes to better performance. When DATAISIZE is the largest, 4,194,394 and LOCALSIZE is 256, it has the best performance.

The second graph shows the relationship between performance and the number of work-groups. It identifies a specific range of the LOCALSIZE and DATASIZE where you can expect the best performance. When operating in this range, we can optimize the performance of the parallel computing tasks. However, beyond this range, the benefit of adding more LOCALSIZE decreases.

4. What difference does the size of the data make?

The size of the data significantly affects the performance. With small data size such as 4096, the GPU is not fully and effectively utilized, and this leads to lower performance. As the data size increases to higher values such as 65,536 to 262,144, the performance improves because of the better GPU utilization. Lastly, with large data sizes greater than 1,048,576, the GPU almost achieves optimal utilization and gains a significant performance.

5. What difference does the size of each work-group make?

For the size of work-group, larger work-group sizes do not necessarily imply better performance, it affects the performance in different ways. When the LOCALSIZE is small (less than 32), the GPU is not fully utilized which leads to lower performance. As it increases to around 32 to 128, the performance gets better because GPU can handle more tasks at once. However, if the LOCALSIZE gets too large such as 256, the performance can drop again. This might be because managing larger work-groups takes more effort and can slow things down.

6. Why do you think the patterns look this way?

The patterns look like this because of how GPU handles different sizes of data and work-groups. With small data sizes, GPU is not utilized very well, so the performance is low. As the data size gets larger, the GPU can process more data in parallel, thus the performance improves. However, work-groups matter as well. Smaller work-groups do not leverage GPU's capability, while medium size of work-groups (32 to 128) utilized it better and improve performance. But if the work-groups get too large, the GPU spends too much time managing them, which might slow things down. All things considered, the best performance happens when both the data size and work-groups size are just right for the GPU to work efficiently without too much management effort.
